## Abstract

Abdominal anatomy segmentation is crucial for numerous applications from computer-assisted diagnosis to image-guided surgery. In this context, we address fully-automated multi-organ segmentation from abdominal CT and MR images using deep learning. The proposed model extends standard conditional generative adversarial networks. Additionally to the discriminator which enforces the model to create realistic organ delineations, it embeds cascaded partially pre-trained convolutional encoder-decoders as generator. Encoder fine-tuning from a large amount of non-medical images alleviates data scarcity limitations. The network is trained end-to-end to benefit from simultaneous multi-level segmentation refinements using auto-context. Employed for healthy liver, kidneys and spleen segmentation, our pipeline provides promising results by outperforming state-of-the-art encoder-decoder schemes. Followed for the Combined Healthy Abdominal Organ Segmentation (CHAOS) challenge organized in conjunction with the IEEE International Symposium on Biomedical Imaging 2019, it gave us the first rank for three competition categories: liver CT, liver MR and multi-organ MR segmentation. Combining cascaded convolutional and adversarial networks strengthens the ability of deep learning pipelines to automat-

ically delineate multiple abdominal organs, with good generalization capability. The comprehensive evaluation provided suggests that better guidance could be achieved to help clinicians in abdominal image interpretation and clinical decision making.

*Keywords:* multi-organ segmentation, convolutional encoder-decoders, adversarial learning, cascaded networks, abdominal images

---

## 1. Introduction

The development of non-invasive imaging technologies over the last decades has opened new horizons in studying abdominal anatomical structures. Segmentation has become a crucial task in abdominal image analysis with numerous applications including computer-assisted diagnosis, surgery planning (e.g. organ pre-evaluation for resection or transplantation), visual augmentation, extraction of quantitative indices or image-guided interventions [1]. In particular, the precise delineation of abdominal solid visceral organs including liver, kidneys and spleen for localization, volume assessment or follow-up purposes has critical importance. However, the analysis of Computed Tomography (CT) and Magnetic Resonance (MR) abdominal imaging datasets is challenging and time-consuming for clinicians since the abdomen is a complex body space. Robust automatic abdominal image segmentation is required to guide image interpretation, facilitate clinical decision making and improve patient care while avoiding traditional manual delineation efforts.

In this area, many interactive, semi- and fully-automated methods have been proposed with diverse methodologies including statistical shape models [3], multi-atlas segmentation [4] or machine learning [5] techniques. More recently, outstanding performance has been reached in almost all medical image analysis tasks using deep learning [6]. Despite the large variability in abdominal organ shape, size, location and texture, abdominal multi-organ segmentation has naturally benefited from this massive trend [7, 8, 9, 10]. Compared to conventional machine learning, the need for hand-crafted features no longer remains neces-

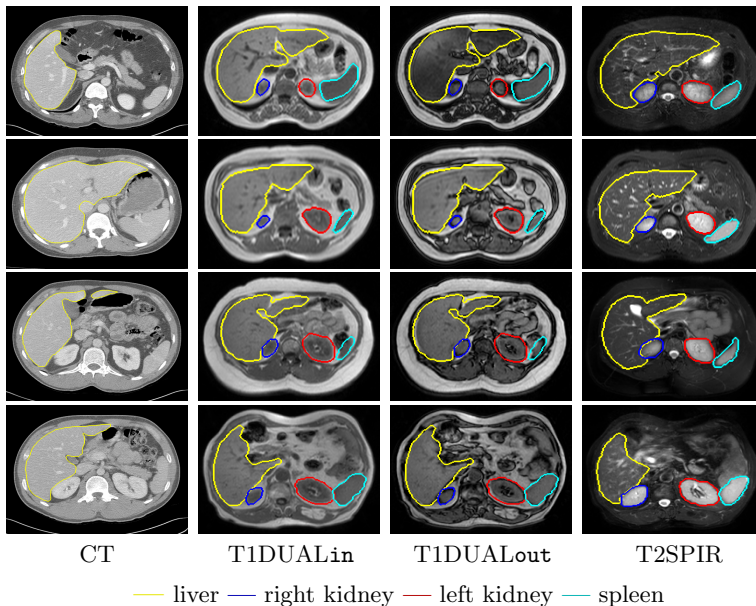

Figure 1: Samples of healthy abdominal CT and MR (T1-DUAL<sub>in/out</sub>, T2-SPIR) images arising from the CHAOS dataset [2], provided with ground truth organ delineations.

sary. In particular, huge efforts have been devoted to automatic segmentation  
25 based on variants of Fully Convolutional Networks (FCN) [11]. Recent archi-  
tecture comprise a regular FCN to extract multi-scale features, followed by an  
up-sampling branch that enables to recover the input resolution through up-  
convolutions [6]. In the medical image processing community, UNet [12] is one  
of the most well-known approach among such Convolutional Encoder-Decoders  
30 (CED). Able to learn from relatively small datasets, CED architectures are the  
most likely to automatically infer high-level knowledge involved by radiologists  
when interpreting abdominal images.

Despite intensive developments in deep learning, it remains difficult to judge  
the effectiveness of deep networks for abdominal multi-organ segmentation since  
35 they are mainly assessed on one single organ only (liver most often), one sin-  
gle modality (usually CT) and/or relatively small and private datasets. Their  
robustness to delineate multiple abdominal structures from different modalities  
and to manage strong inter-subject variability is therefore under-investigated.  
Rather than organ or modality-specific strategies, the development of more com-

40 prehensive and generic computational models is needed [13]. Few challenges including the Combined Healthy Abdominal Organ Segmentation (CHAOS) challenge<sup>1</sup> [2], organized in conjunction with the IEEE International Symposium on Biomedical Imaging (ISBI) 2019, has been proposed to motivate further work on this perspective by making available a dataset (Fig.1) to segment multiple  
45 organs from two imaging modalities (CT, MR with T1-DUAL and T2-SPIR sequences) acquired for unpaired healthy subjects. Towards efficient combined segmentation and based on this unique dataset, we target robust and generic deep learning architectures for two main purposes: 1- segmentation of liver from CT scans and 2- segmentation of four abdominal organs (liver, right kidney, left  
50 kidney, spleen) from MR images.

The proposed healthy abdominal multi-organ segmentation methodology comprises three key aspects. First, deeper CED architectures using encoders pre-trained on non-medical data and extending the UNet [12] baseline are investigated. Second, we embed this architecture into a cascaded framework using  
55 auto-context and end-to-end training to benefit from simultaneous multi-level segmentation refinements. Third, such cascaded pipeline is used as generator within a conditional Generative Adversarial Network (cGAN). The resulting model thus includes a discriminator to strengthen the ability of the generative part to create delineations as realistic as possible. The step-by-step evaluation  
60 provided for each contribution in both CT and MR modalities highlights better performance than state-of-the-art encoder-decoder schemes. The pipeline also gave us the first rank for three CHAOS competition categories<sup>2</sup> (liver CT, liver MR and multi-organ MR segmentation) [2] which suggests that the proposed computational deep models can offer new insights for abdominal image  
65 interpretation and clinical decision making, in various computer-assisted tasks.

## 2. Related works

Computational abdominal organ segmentation has attracted considerable attention over the last decades. This craze led to the development of a wide range of **methodologies**, from interactive to semi- and fully-automated [14]. Before the recent development of machine and deep learning, abdominal organ segmentation has often been carried out using statistical shape models [15, 3] to capture and then fit organ shapes through anatomical correspondences. Since deformations and limited datasets may prevent those models from managing the strong variability of abdominal organ shapes, aligning and merging manually segmented images could be followed as an alternative. Specifically, multi-atlas segmentation consists in leveraging label atlases through image registration and statistical fusion [16]. Applied to abdominal data, coarse-to-fine [17], region-wise local atlas selection [18], Selective and Iterative Method for Performance Level Estimation (SIMPLE) [4, 19] or dictionary learning and sparse coding [20] techniques can be employed to alleviate substantial registration errors. Nevertheless, robust inter-subject abdominal image registration is a challenging, computational intense and not yet solved issue [21] due to the diversity of organ shape, size, location and texture. This mainly explains the success of registration-free methods whose aim is to learn feature distributions that characterize abdominal anatomy from un-registered images.

Among registration-free methods, computational power and data availability have enabled the rise of machine learning techniques *via* voxel- [5, 22], patch- [23] or supervoxel-wise [24] classifiers. These methods require hand-crafted features and therefore, specialized knowledge to delineate structures from medical images. Conversely, deep Convolutional Neural Networks (CNN), **data-driven learning** models formed by multi-layer neural networks, automatically learn complex hierarchical features from data [25]. In this direction, huge efforts have been devoted to automatic segmentation based on variants of Fully Convolutional Networks (FCN) [11]. Further improvements are reached with architectures comprising a regular FCN to extract features, followed by an up-sampling

part which recovers the input resolution using up-convolutions [6]. UNet [12] and its 3D counterparts [26, 27] are among the most well-known Convolutional Encoder-Decoders (CED) in the medical community. They exploit **long-range shortcuts** to concatenate features between contracting and expanding paths for  
100 improving localization accuracy while allowing faster convergence.

CED networks have been widely adopted for automatic abdominal organ segmentation, as in [7] where 3D UNet [27] is exploited in a two-stage hierarchical fashion for multi-organ delineation purposes. Combining densely linked layers and shallow 3D UNet architecture [8] enables high-resolution activation  
105 maps through memory-efficient dropout and feature re-use. Some approaches consider post-processing steps for further contour refinement by exploiting organ probability maps arising from 3D CED as features for Conditional Random Field (CRF) [28], level-set [9] or graph-cut [29] models. Organ-attention networks with reverse connections followed by statistical fusion [10] tend to reduce  
110 uncertainties at weak boundaries and deal with relative organ size variations.

Feeding deep networks with volumetric images obviously faces memory and computational issues. Since increasing the network depth to extract discriminative features with a larger receptive field cannot be done *ad-infinitum*, many methods rely on small patches or downsampled images resulting in a significant  
115 loss of spatial context [8]. Reaching accurate organ delineations, however, requires to extract high-level contextual information, as do radiologists visually. Several key contributions in semantic segmentation arose to mimic visual medical image interpretations more closely. First, structure delineation can exploit transfer learning from large non-medical datasets [30, 31] to reduce the  
120 data scarcity issue while improving model generalizability [32]. Second, stacking multiple CEDs encourages the integration of more representative multi-level information [33, 34]. In particular, cascades of deep CEDs can embed auto-context [35] to fuse various amounts of spatial context **using** posterior probabilities resulting from one CED block to the subsequent. Third, conditional generative  
125 adversarial networks extends standard image-to-image translation [36] by including a discriminator whose role is to enforce the model to generate realis-

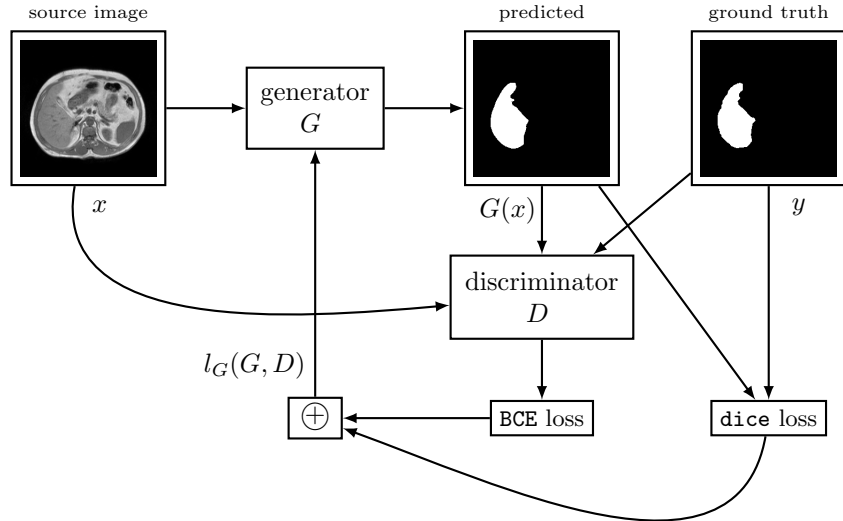

Figure 2: Conditional generative adversarial networks combining Dice and Binary Cross Entropy (BCE) losses for abdominal organ segmentation. The + symbol indicates that the loss function  $l_G(G, D)$  for the generator  $G$  is a weighted sum of Dice and BCE metrics (Eq.1).

tic outputs. Successfully applied to medical images [37, 38, 39], introducing adversarial training to semantic segmentation not only leverages overall delineation performance but also alleviates high-order spatial incorrectness such as inaccurate boundaries or isolated false positives [40, 41]. In the context of abdominal image analysis, all these avenues represent promising methodological developments to achieve more generic computational models for CT and MRI multi-organ segmentation.

### 3. Methods

#### 3.1. Conditional generative adversarial networks

Recent works including [37, 38, 39, 41] have demonstrated the feasibility of image-to-image translation [36] based on conditional Generative Adversarial Networks (cGAN) for medical image segmentation purposes. cGAN architectures (Fig.2) are made of a generator which provides segmentation masks through encoding and decoding layers and a discriminator (Fig.3) which assesses if a given segmentation mask is synthetic or real. Thus, the adversarial

Figure 3: Discriminative part of conditional generative adversarial networks.

network learns to discriminate real (i.e. ground truth) from synthetic delin-  
 eations (those arising from the generator) to enforce the generative part to  
 create segmentation masks as plausible as possible. **Contrary to standard iter-**  
 145 **ative post-processing schemes such as Conditional Random Field (CRF) [28] or**  
**level-set [9], this refinement is performed in an end-to-end fashion [41].**

cGAN pipelines usually use UNet [12] as generator  $G$  (Fig.4a). Its sym-  
 metrical architecture comprises an encoder which gradually reduces the spatial  
 dimension using pooling layers, a decoder progressively recovering object details  
 and initial resolution as well as **long-range shortcuts** which concatenate features  
 150 between contracting and expanding paths. Specifically, UNet consists of sequen-  
 tial layers including  $3 \times 3$  convolutional layers followed by Rectified Linear Unit  
 (ReLU) activations. Spatial size is reduced using  $2 \times 2$  max pooling layers. The  
 first convolutional layer generates 32 channels [12]. This number doubles after  
 155 each pooling as the network deepens. Following [37], the discriminator  $D$   
 consists of five  $4 \times 4$  convolutional layers followed by leaky ReLU activation func-  
 tions and batch normalization (Fig.3). The discriminator inputs are the concatena-  
 tion of both source images and ground truth or predicted binary masks to be  
 evaluated. The output is an array where each value is defined between 0 (fake)  
 160 and 1 (plausible or real) and corresponds to the degree of segmentation likeli-  
 hood for a given image **crop and its associated segmentation mask**. Let  $x$  and  $y$   
 be the source images and ground truth delineation masks,  $\lambda = 150$  **an empir-**  
**ically set** weighting factor [37],  $G(x)$  and  $D(x, G(x))$  the outputs of  $G$  and  $D$ ,  
 $l_{\text{dice}}$  the Dice loss estimated by comparing predicted and ground truth masks.

165 As in [41, 37], the loss function  $l_G(G, D)$  for the generator  $G$  is defined as the following combination:

$$l_G(G, D) = \mathbb{E}_{x,y} [-\log(D(x, G(x)))] + \lambda \mathbb{E}_{x,y} [l_{\text{dice}}(G(x), y)] \quad (1)$$

Minimizing  $l_{\text{dice}}$  tends to provide rough organ shape predictions whereas maximizing  $\log(D(x, G(x)))$  aims at improving contour delineations. The loss function for the discriminator  $D$  is such that:

170

$$l_D(G, D) = \mathbb{E}_{x,y} [-\log(D(x, y))] + \mathbb{E}_{x,y} [-\log(1 - D(x, G(x)))] \quad (2)$$

The optimizer fits  $D$  through Binary Cross Entropy (BCE) using estimated and ground truth masks. It maximizes loss values for ground truth ( $\log(D(x, y))$ ) and minimizes loss values for generated ( $-\log(1 - D(x, G(x)))$ ) masks. Optimization is performed sequentially by alternating at each batch gradient descents on  $G$  and  $D$  [42]. To further improve cGAN abilities to extract contours from the abdominal anatomy, investigations on more robust generators than traditional UNet are needed.

175

### 3.2. Partially pre-trained generator

180 CED architectures dedicated to medical image segmentation are typically trained from scratch, relying on randomly initialized weights. Since the amount of available images cannot be endlessly extended, reaching a generic model without over-fitting is therefore challenging. As deep classification networks which usually involve model pre-trained on large datasets, the encoder part of CEDs can be replaced by a classification network whose weights are previously trained

185

can be replaced by a classification network whose weights are previously trained on an initial classification task [30]. It exploits transfer learning and fine-tuning from large datasets like ImageNet [43] towards better semantic segmentation. In the literature, the encoder has been already replaced by pre-trained VGG-11 [30] or WideResnet-38 [44] networks. Our previous study [31] exploits pre-trained

Figure 4: Extension of UNet [12] (a) by exploiting as encoder a slightly modified VGG-19 [45] without (b) and with (c) weights pre-trained on ImageNet [43]. The decoder is modified to get a symmetrical construction while keeping **long-range shortcuts**.

190 VGG-16 encoders and reveals significant improvements compared to their randomly weighted counterparts.

This approach can be further improved by extending standard UNet [12] by a deeper network from the VGG family [45] as encoder: the VGG-19 architecture. Compared to UNet (Fig.4a), the first convolutional layer of v19UNet (Fig.4b) 195 generates 64 channels instead of 32. The number of channels doubles after each max pooling until it reaches 512 (256 for UNet). After the second max pooling, the number of convolutional layers differs from UNet with patterns of 4 consecutive layers instead of 2. Compared to VGG-19 [45], top layers including fully-connected layers and softmax are omitted. The three last convolutional 200 VGG-19 layers serve as central part to separate **the** contracting and expanding paths. To improve performance, this encoder branch is pre-trained on ImageNet [43] to get **the CED architecture referred to v19pUNet** (Fig.4c). Pre-training this encoder using more than 1 million non-medical data collected for object recognition purposes improves predictive performance on abdominal data and

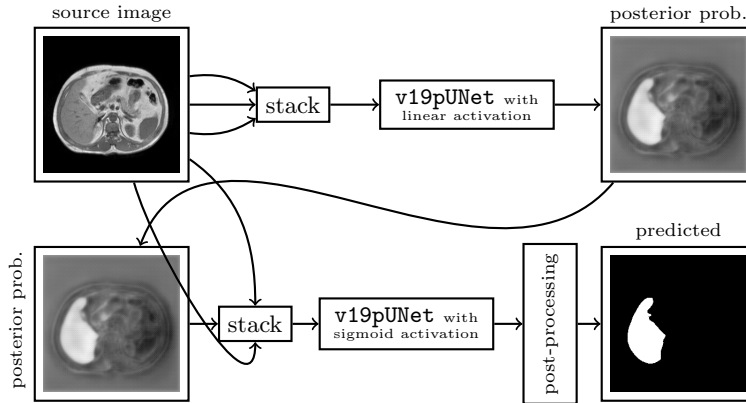

Figure 5: Cascaded convolutional encoder-decoders with auto-context to exploit multi-level contextual information. **The stack blocks consist in concatenating multiple inputs.**

205 requires less training time to reach convergence. In practice, axial slices are extended from single grayscale channel to 3 channels by repeating the same content to fit the RGB ImageNet image **depth**.

To get a symmetrical construction while keeping **long-range shortcuts** (Fig.4c), the decoder branch is extended in the same fashion by adding 4 convolutional  
 210 layers and more features channels. Contrary to encoder weights which are initialized **through** ImageNet pre-training, decoder weights are set randomly. A final  $1 \times 1$  convolutional layer with sigmoid activation function achieves pixel-wise segmentation at native resolution.

### 3.3. Cascaded generator with auto-context

215 Managing long-range spatial context is key to improve abdominal organ delineations [24]. However, increasing *ad-infinitum* the network depth to exploit larger receptive fields is not suitable for memory and computational issues. Alternatively, in the same spirit of [34], we propose to process abdominal images using a cascade of deep CEDs to exploit multi-level contextual information  
 220 (Fig.5). Our strategy, referred to  $v19pUNet_{1-1}$ , consists in combining two partially pre-trained  $v19pUNet$  networks with auto-context [35], i.e. using posterior probabilities resulting from the first  $v19pUNet$  as features for the second one [46]. It extends with more complex architectures a proof-of concept given in [47] us-

ing standard UNet ( $\text{UNet}_{i-1}$ ). The sigmoid activation of the first **v19pUNet** used  
225 in the last  $1 \times 1$  convolution layer (Fig.4c) is replaced by a linear function to  
generate continuous output maps. These maps are normalized, concatenated to  
source images and given as inputs of the second **v19pUNet** which is trained to  
give final organ delineations. **In practice, since the second CED requires 3-layers  
volumes as inputs due to its encodeur pre-trained on ImageNet, we concatenate  
230 the posterior probability map with the source image whose content is replicated  
twice (stack block in Fig.5).** Instead of training both models separately [46],  
our pipeline is trained end-to-end to exploit simultaneous multi-level segmen-  
tation refinements. Making the first **v19pUNet** generating continuous instead  
of binary outputs propagates pixel-wise confidence information to the second  
235 **v19pUNet** and postpones the final segmentation decision to the pipeline ending  
part. Contrary to [34], both networks process source images at full-resolution.  
Moreover, we keep the largest connected segmented area as post-processing.

We propose to use this cascaded partially pre-trained **v19pUNet<sub>i-1</sub>** model as  
generator within the cGAN pipeline (**cGv19pUNet<sub>i-1</sub>**). Robustness and general-  
240 ization capabilities need to be assessed for abdominal multi-organ segmentation.

## 4. Results and discussion

### 4.1. Validation setup

Results are provided using the dataset<sup>3</sup> arising from the CHAOS challenge  
[2], collected by the Department of Radiology, Dokuz Eylul University Hospi-  
245 tal, Izmir, Turkey **and involving 80 patients**. 40 abdominal CT scans acquired  
at portal venous phase after contrast agent injection are used with ground  
truth liver segmentation. The dataset also includes 40 T1-DUAL in phase  
(T1-DUALin), 40 T1-DUAL oppose phase (T1-DUALout) and 40 T2-SPIR  
abdominal MR images with ground truth delineations for liver, right kidney,  
250 left kidney and spleen. Three radiology experts (10, 12 and 28 years of experi-

---

<sup>3</sup>CHAOS data available at <https://doi.org/10.5281/zenodo.3362844>

ence) were involved for manual segmentation. Final ground truth masks were obtained through majority voting. T1-DUAL<sub>in</sub> and T1-DUAL<sub>out</sub> images are registered. Conversely, T1-DUAL and T2-SPIR sequences are not registered. Following the CHAOS challenge rules, CT and MR datasets are divided into training and test subsets, with a ratio of 50%.

Except for DeepMedic [48], VNet [26] and denseVNet [8] which process data in 3D, evaluated models independently process 2D axial slices and produce 2D segmentation masks which are then stacked together to recover 3D volumes. Image size for axial slices are  $256 \times 256$  or  $288 \times 288$  pixels for MR images,  $512 \times 512$  for CT examinations. The number of axial slices varies from 26 to 50 (resp. 78 to 294) and slice thickness is between 4.4 and 8.0 (resp. 2.0 and 3.2) millimeters for MR (resp. CT) images.

Let  $S$  and  $G$  deal with segmentation results and ground truth. To assess standard CED (DeepMedic [48], VNet [26], denseVNet [8], UNet [12]), deeper CED without or with encoder pre-training (v16UNet, v16pUNet [31], v19UNet, v19pUNet), CED using nested and dense skip connections (v19UNet+, v19pUNet+ [49]), cascaded CED (UNet<sub>1-1</sub> [47], v16pUNet<sub>1-1</sub>, v19pUNet<sub>1-1</sub>) and cGAN with partially pre-trained cascaded CED as generator (cGv16pUNet<sub>1-1</sub>, cGv19pUNet<sub>1-1</sub>), the accuracy of abdominal organ segmentation is quantified based on Dice coefficient (**dice**) estimated following  $\frac{2|S \cap G|}{|S| + |G|}$  where  $|\cdot|$  denotes cardinality, relative absolute volume difference (**RAVD**) comparing  $S$  and  $G$  such as  $\text{RAVD} = \frac{\text{abs}(|S| - |G|)}{|G|}$ , average and maximum symmetric surface distances (**ASSD**, **MSSD**) which correspond to the average (resp. maximum) Hausdorff distance between border voxels in  $S$  and  $G$ . These metrics tend to provide an overall assessment of the involved networks. Following [2], we also provide model ranking scores by averaging all metrics after having transformed values to span the  $[0, 100]$  interval so that higher values correspond to better segmentation. To discard unacceptable accuracy and increase metric sensitivity [2], thresholds are set up according to intra/inter-expert similarities: **dice** > 80%, **RAVD** < 5%, **ASSD** < 15mm and **MSSD** < 60mm. Metrics outside the threshold range get zero points. Scores reached for multi-organ segmentation are obtained by averag-

ing **the scores obtained** for each organ. Similarly, scores for MR images are the average between results arising from T1-DUALin/out and T2-SPIR **modalities**.

In our experiments, a given model is dedicated to one single modality (T1-DUALin/out, T2-SPIR, CT) and one single organ (liver, right kidney, left kidney, spleen). Each model thus performs binary instead of multi-class segmentation to extract robust organ-specific features. In addition, experiments on the T1-DUAL modality stack together T1-DUALin and T1-DUALout images as model inputs since both phases are registered. When 3 channels are required, as for v16(p)UNet, the third channel consists of the T1DUALin image duplication. For CT and T2-SPIR, image content is replicated twice.

Deep CEDs are trained using data augmentation to teach networks efficient invariance and robustness properties [12]. Training axial slices undergo random scaling, rotation, shearing and shifting operations. 100 augmented images are produced for a single training slice. For CT (MR) images, models are trained with 6 (20) epochs, a batch size of 3 (5) images, an *Adam* optimizer with  $10^{-5}$  as learning rate and a fuzzy Dice score as loss function. Models were implemented using Keras and trained using **a single** Nvidia GeForce GTX 1080 Ti GPU.

#### 4.2. Evaluation on clinical data

**CT and MR liver segmentation.** Quantitative metric and score values are provided in Tab.1 for liver CT/MR delineations. For both modalities, standard architectures including DeepMedic, VNet, denseVNet and UNet are outperformed by deeper (v16/v16pUNet, v19/v19pUNet) and cascaded (UNet<sub>1-1</sub>) networks which indicates that better predictive performance and generalizability are reached **using** more complex models. In one hand, comparisons between v16/v19UNet and their partially pre-trained extensions (v16p/v19pUNet) reveals that pre-training the encoder using non-medical ImageNet data makes the network converge towards a better solution. In particular, large gains in terms of **dice** (91.60 to 94.07%) and **ASSD** (2.96 to 1.70mm) are reported for MR images between v16UNet and v16pUNet. In the other hand, extending UNet into a cascaded pipeline (UNet<sub>1-1</sub>) **with** auto-context and end-to-end-training al-

Table 1: Quantitative assessment of DeepMedic [48], VNet [26], denseVNet [8], UNet [12], v16UNet, v16pUNet [31], v19UNet, v19pUNet, v19UNet+ [49], v19pUNet+ [49], UNet<sub>1-1</sub> [47] and proposed v16pUNet<sub>1-1</sub>, v19pUNet<sub>1-1</sub>, cGv16pUNet<sub>1-1</sub>, cGv19pUNet<sub>1-1</sub> and M0vpUNet architectures for healthy liver segmentation in CT and MR images. Bold and underline results indicate first and second best scores.

lows to take advantage of multi-level context, with score improvements from 79.07 (58.02) to 81.28% (63.05%) in CT (MR). v19UNet and v19pUNet give better or slightly similar performance than their nested and dense counterparts (v19/v19pUNet+) which suggests that the great complexity brought by such heavy architectures [49] is not useful to provide relevant liver contours.

By combining these three contributions (deeper model, encoder pre-training, cascaded architecture), v16pUNet<sub>1-1</sub> (v19pUNet<sub>1-1</sub>) discriminates more efficiently liver areas from surrounding structures by achieving the best score for CT (MR) scans with 85.53% (70.05%). Embedding v16pUNet<sub>1-1</sub> (v19pUNet<sub>1-1</sub>) into a cGAN pipeline for CT (MR) liver segmentation gives broadly similar results but provides the second best scores. We note that cGv16pUNet<sub>1-1</sub> reaches the best dice (97.95%) and similar ASSD (0.76mm) in CT. In MR, the best RAVD (3.49%) is obtained using cGv19pUNet<sub>1-1</sub>.  $\lambda = 150$  was selected as in [37] to provide a good balance between  $\mathbb{E}_{x,y}[-\log(D(x, G(x)))]$  and  $\mathbb{E}_{x,y}[l_{\text{dice}}(G(x), y)]$  in Eq.1.

Qualitative results for CT and MR liver segmentation are displayed in Fig. 6-7. Compared to standard networks as well as v16pUNet (v19pUNet/v19pUNet+) which are prone to under- or over-segmentation, sometimes combined with unrealistic shapes, better contour adherence and shape consistency are reached by

 — v16pUNet [31] — v16pUNet<sub>1-1</sub> — cGv16pUNet<sub>1-1</sub> ■ liver

Figure 6: Liver CT segmentation using DeepMedic [48], VNet [26], denseVNet [8], UNet [12], v16UNet, v16pUNet [31], proposed v16pUNet<sub>1-1</sub> and cGv16pUNet<sub>1-1</sub>. Ground truth is superimposed in red color.

330 v16pUNet<sub>1-1</sub> (v19pUNet<sub>1-1</sub>) and cGv16pUNet<sub>1-1</sub> (cGv19pUNet<sub>1-1</sub>) whose ability to mimic expert annotations is notable for CT (T1-DUAL and T2-SPIR). The diversity in terms of textures arising in MR images is accurately captured through cascaded partially pre-trained networks despite high similar visual properties with surrounding structures. Moreover, deep networks find it harder to segment abdominal MR compared to CT images due to lower contrast and resolution combined with higher spacing which makes the number of 2D axial slices substantially smaller.

**Abdominal multi-organ MR segmentation.** Tab.2 shows quantitative results for multi-organ MR segmentation. As for liver, the DeepMedic, VNet, denseVNet, UNet, v16UNet and v19UNet networks do not provide the required robustness for organ extraction. In T1-DUAL modality, significant improvements can be noticed using v16pUNet for left kidney, v19pUNet for right kidney and v19pUNet+ for spleen with the best reached scores (63.52, 68.07 and 69.04%) among all schemes. Except for spleen in T2-SPIR, the comparison UNet/UNet<sub>1-1</sub> indicates the appropriateness of exploiting networks in a cascaded manner, as proven for spleen (right kidney) in T1-DUAL (T2-SPIR) whose dice

— DeepMedic [48] — VNet [26] — denseVNet [8] — UNet [12] — v19pUNet  
 — v19pUNet+ [49] — v19pUNet<sub>1-1</sub> — cGv19pUNet<sub>1-1</sub> ■ liver

Figure 7: Liver MRI (T1-DUALin, T2-SPIR) segmentation using DeepMedic [48], VNet [26], denseVNet [8], UNet [12], v19pUNet, v19pUNet+ [49], proposed v19pUNet<sub>1-1</sub> and cGv19pUNet<sub>1-1</sub>. Ground truth is superimposed in red color.

(RAVD) jumps from 81.56 (15.39) to 87.01% (9.04%). The same conclusion arises between v16p/v19pUNet and v16p/v19pUNet<sub>1-1</sub> with, for instance, a strong score  
 350 improvement reached using v19pUNet<sub>1-1</sub> for right kidney in T2-SPIR (68.38 to 72.71%). Cascaded pre-trained cGAN strategies (cGv16p/cGv19pUNet<sub>1-1</sub>) always belong to one of the two best methods in dice, except for left kidney in T1-DUAL. Gains for MSSD in T2-SPIR are highlighted with 11.23mm (10.96) obtained for right kidney (spleen) using cGv19pUNet<sub>1-1</sub> (cGv16pUNet<sub>1-1</sub>). In T1-  
 355 DUAL, cGv19pUNet<sub>1-1</sub> (cGv16pUNet<sub>1-1</sub>) achieves the best RAVD scores for liver and right kidney (spleen). *p*-values obtained using Student’s paired *t* tests for Dice, RAVD, ASSD and MSSD metrics between cGv19pUNet<sub>1-1</sub> and standard CED architectures such as DeepMedic or denseVNet globally confirmed that our contributions bring an added-value with statistical significance. Unsurprisingly, delineating small organs (kidneys) is more challenging than focusing on larger  
 360 ones (liver, spleen). The vicinity between left kidney and spleen further complicates the contouring task. MR segmentation is easier with T2-SPIR than T1-DUAL since relative contrasts between structures is clearly enhanced.

As visually shown in Fig.8, many anomalies are present using standard networks with over (under-) detection issues for DeepMedic (denseVNet) in T2-  
 365

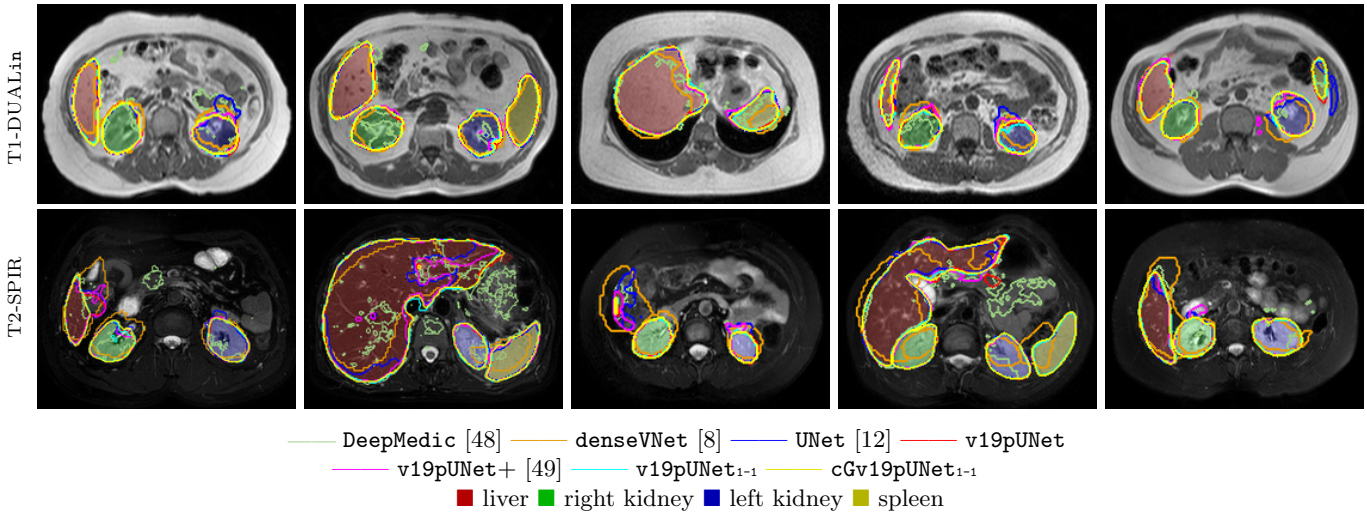

Figure 8: Abdominal multi-organ MRI (T1-DUALin, T2-SPIR) segmentation using DeepMedic [48], denseVNet [8], UNet [12], v19pUNet, v19pUNet+ [49], proposed v19pUNet<sub>1-1</sub> and cGv19pUNet<sub>1-1</sub>. Liver, right kidney, left kidney and spleen ground truth delineations are respectively superimposed in red, green, blue and yellow colors.

SPIR. v19pUNet<sub>1-1</sub> and cGv19pUNet<sub>1-1</sub> show a better behavior than v19pUNet and v19pUNet+ in accurately fitting organ extents and offering plausible shape consistency, especially for bases and apexes where organs appear smaller. Despite visually similar performance compared to v19pUNet<sub>1-1</sub>, cGv19pUNet<sub>1-1</sub> appears slightly better in providing realistic organ contours.

**Towards better multi-organ segmentation.** Under the team name PKDIA, the proposed cGv19pUNet<sub>1-1</sub> pipeline enabled us to win three CHAOS competition categories: liver CT, liver MR and multi-organ MR segmentation [2]. Nevertheless, since global findings are verified with varying degrees depending on the concerned modality or organ, we provide in Tab.3 an overall evaluation through scores and rankings for CT liver, MR liver, right kidney, left kidney, spleen as well as multi-organ segmentation. cGv19pUNet<sub>1-1</sub> indeed appears as the best strategy for MR multi-organ delineation purposes that reinforces the idea that combining deeper (v19) cascaded partially pre-trained convolutional and adversarial networks globally strengthens the generalization abilities of deep

M0vpUNet	85.53	*	70.17	*	70.39	*	64.77	*	69.92	*	68.78	*

Table 3: Scoreboard and ranking of DeepMedic [48], denseVNet [8], UNet [12], v16UNet, v16pUNet [31], v19UNet, v19pUNet, v19UNet+ [49], v19pUNet+ [49], UNet<sub>1-1</sub> [47], proposed v16pUNet<sub>1-1</sub>, v19pUNet<sub>1-1</sub>, cGv16pUNet<sub>1-1</sub>, cGv19pUNet<sub>1-1</sub> and M0vpUNet for healthy abdominal organ (liver, right kidney, left kidney, spleen) segmentation in CT and MR images. Bold, underline and italic results indicate first, second and third best scores.

learning pipelines. Except for left kidney where v16pUNet performs the best (64.05%), the first rank is always attributed to one of the proposed cascaded pre-trained scheme: v16pUNet<sub>1-1</sub> for CT liver, v19pUNet<sub>1-1</sub> for MR liver and right kidney (69.45%), cGv16pUNet<sub>1-1</sub> for MR spleen (68.9%) and cGv19pUNet<sub>1-1</sub> for MR multi-organ (66.86%) segmentation.

By combining the best sequence- and organ-specific networks towards better Multi-Organ (M0) segmentation, we obtain the so-called M0vpUnet computational model including v16pUNet<sub>1-1</sub> for liver in CT (Tab.1) as well as respectively for T1-DUAL and T2-SPIR cGv19pUNet<sub>1-1</sub> and v19pUNet<sub>1-1</sub> for liver, v19pUNet and v19pUNet<sub>1-1</sub> for right kidney, v16pUNet and cGv16pUNet<sub>1-1</sub> for left kidney, v19pUNet+ and cGv16pUNet<sub>1-1</sub> for spleen (Tab.2). The global ranking score reached by cGv19pUNet<sub>1-1</sub> for multi-organ MR segmentation is further improved about 2% with M0vpUnet, up to 68.78% (Tab.3). Visually comparing manual and M0vpUnet delineations in Fig.9 further supports the validity of our combined computational model. Outstanding performance is reached in terms of boundary adherence and shape consistency which suggests that integrating M0vpUnet as a guidance tool into clinical routine could greatly help clinicians for abdominal image interpretation.

— MOvpUNet ■ liver ■ right kidney ■ left kidney ■ spleen

Figure 9: Liver CT and abdominal multi-organ MRI (T1-DUALin/out, T2-SPIR) segmentation using the proposed MOvpUNet. Liver, right kidney, left kidney and spleen ground truth delineations are superimposed in red, green, blue and yellow colors.

## 400 5. Conclusion

This work tackles fully-automated abdominal organ CT and MR segmentation with deep learning. Standard segmentation networks are extended to cascades of partially pre-trained deep convolutional encoder-decoders. Encoder fine-tuning from a large amount of non-medical images improves predictive performance while alleviating data scarcity limitations. The cascaded architecture exploits multi-level contextual information through auto-context and end-to-end training. Such model is used as generator in a conditional generative adversarial network to further encourage the generative part to provide plausible organ delineations. Results highlight promising performance by outperforming state-of-the-art encoder-decoder schemes. Employed for the Combined Healthy Abdominal Organ Segmentation (CHAOS) challenge, our contributions reached the first rank for liver CT, liver MR and multi-organ MR segmentation competition categories. The proposed pipeline has the potential to support guidance for abdominal image interpretation, clinical decision making and patient care improvement while avoiding manual delineation efforts. Further work includes the evaluation of such deep models to other anatomical structures from the abdomen (pancreas, gallbladder) and the gastro-intestinal tract (esophagus, stomach, duodenum) arising from healthy and pathological subjects. More globally, our pipeline could be easily extended to other tissue types and imaging modalities to provide relevant clinical decision support. Methodological perspectives on unpaired cross-modality (CT, MR...) medical image segmentation with compact architectures could deserve further investigation to take advantage of multi-tasking properties of deep models as well as a larger amount of available data. Extending adversarial frameworks to incorporate anatomical priors using topological or shape constraints should also offer new insights to manage the strong diversity of abdominal organ appearance.

## Conflicts of interest
